

ON THE C*-ALGEBRA GENERATED BY TOEPLITZ OPERATORS AND FOURIER MULTIPLIERS ON THE HARDY SPACE OF A LOCALLY COMPACT GROUP

UĞUR GÜL

Dedicated to Prof. Aydın Aytuna on the occasion of his 65th birthday

ABSTRACT. Let G be a locally compact abelian Hausdorff topological group which is non-compact and whose Pontryagin dual Γ is partially ordered. Let $\Gamma^+ \subset \Gamma$ be the semigroup of positive elements in Γ . The Hardy space $H^2(G)$ is the closed subspace of $L^2(G)$ consisting of functions whose Fourier transforms are supported on Γ^+ . In this paper we consider the C*-algebra $C^*(\mathcal{T}(G) \cup F(C(\Gamma^+)))$ generated by Toeplitz operators with continuous symbols on G which vanish at infinity and Fourier multipliers with symbols which are continuous on one point compactification of Γ^+ on the Hilbert-Hardy space $H^2(G)$. We characterize the character space of this C*-algebra using a theorem of Power.

INTRODUCTION

For a locally compact abelian Hausdorff topological group G whose Pontryagin dual Γ is partially ordered, one can define the positive elements of Γ as $\Gamma^+ = \{\gamma \in \Gamma : \gamma \geq e\}$ where e is the identity of the group G and the Hardy space $H^2(G)$ as

$$H^2(G) = \{f \in L^2(G) : \hat{f}(\gamma) = 0 \quad \forall \gamma \notin \Gamma^+\}$$

where \hat{f} is the Fourier transform of f . It is not difficult to see that $H^2(G)$ is a closed subspace of $L^2(G)$ and since $L^2(G)$ is a Hilbert space there is a unique orthogonal projection $P : L^2(G) \rightarrow H^2(G)$ onto $H^2(G)$.

This definition of the Hardy space $H^2(G)$ is motivated by Riesz theorem in the classical cases when $G = \mathbb{T}$ i.e when G is the unit circle, which characterizes the Hardy class functions among $f \in L^2(\mathbb{T})$ as the space of functions whose negative Fourier coefficients vanish and by the Paley-Wiener theorem when $G = \mathbb{R}$, the real line since the group Fourier transform is the Fourier series when $G = \mathbb{T}$ and coincides with the Euclidean Fourier transform when $G = \mathbb{R}$.

One can extend the theory of Toeplitz operators to this setting by defining a Toeplitz operator with symbol $\phi \in L^\infty(G)$ as $T_\phi = PM_\phi$ where M_ϕ is the multiplication by ϕ and P is the orthogonal projection of L^2 onto H^2 . Such a definition was first considered by Coburn and Douglas in [2]. However the Toeplitz operators considered in [2] were more general since no partial order was assumed on the dual Γ whereas the Hardy space was defined as the space of functions whose

Fourier transforms are supported on a fixed sub-semigroup Γ_0 of Γ . The definition of Hardy space of groups whose duals are partially ordered and their Toeplitz operators were introduced and studied by Murphy in [7] and [8]. However in these papers [7] and [8], Murphy studies the case where G is compact. In this paper we will study the case where G is not compact. One very important assumption that we will make is that Γ^+ separates the points of G , i.e. for any $t_1, t_2 \in G$ satisfying $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$.

The Toeplitz C^* -algebra of a locally compact group is defined as

$$\mathcal{T}(G) = C^*(\{T_\phi : \phi \in C_0(G)\} \cup \{I\})$$

where $C_0(G)$ is the space of continuous functions vanishing at infinity and I is the identity operator. In the study of this Toeplitz C^* -algebra, the most important notions are the commutator ideal $\text{com}(G) = I^*(\{T_\phi T_\psi - T_\psi T_\phi : \phi, \psi \in C_0(G)\})$, the semi-commutator ideal $\text{scom}(G) = I^*(\{T_{\phi\psi} - T_\psi T_\phi : \phi, \psi \in C_0(G)\})$ and the symbol map $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/\text{com}(G)$, $\Sigma(\phi) = [T_\phi]$ where \dot{G} is the one point compactification of G and $[T_\phi]$ denotes the equivalence class of T_ϕ modulo $\text{com}(G)$. It is not difficult to see that $\text{com}(G) \subseteq \text{scom}(G)$. We start by proving the following important result whose proof is adapted from [6]:

Lemma 1. *Let G be a locally compact abelian Hausdorff topological group whose Pontryagin dual Γ is partially ordered and let Γ^+ be the semigroup of positive elements of Γ . Suppose that Γ^+ separates the points of G i.e. for any $t_1, t_2 \in G$ with $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$. Let $\text{com}(G)$ and $\text{scom}(G)$ be the commutator and the semi-commutator ideal of the Toeplitz C^* -algebra $\mathcal{T}(G)$ respectively. Then*

$$\text{com}(G) = \text{scom}(G)$$

It is shown in [2] and [7] that $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/\text{com}(G)$ is an isometry but is not a homomorphism since it may not preserve the multiplication. However $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/\text{scom}(G)$ is a homomorphism and combining this fact with Lemma 1 above we deduce that the symbol map $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/\text{com}(G)$ is an isometric isomorphism which means that

$$M(\mathcal{T}(G)) = \dot{G}$$

where $M(A)$ is the character space of a C^* -algebra A .

We introduce another class of operators acting on $H^2(G)$ which are called “Fourier multipliers”. These operators in the classical case $G = \mathbb{R}$ were introduced in [4]. The space of Fourier multipliers is defined as

$$F(C(\Gamma^+)) = \{D_\theta = \mathcal{F}^{-1} M_\theta \mathcal{F} \mid_{H^2(G)} : \theta \in C(\Gamma^+)\}$$

where $\mathcal{F} : L^2(G) \rightarrow L^2(\Gamma)$ is the Fourier transform. By Plancherel theorem it is not difficult to see that the image $\mathcal{F}(H^2(G))$ of $H^2(G)$ under the Fourier transform is equal to $L^2(\Gamma^+)$. Again it is not difficult to see that $F(C(\Gamma^+))$ is isometrically isomorphic to $C(\Gamma^+)$. This means that

$$M(F(C(\Gamma^+))) = \Gamma^+$$

Lastly we consider the C^* -algebra generated by $\mathcal{T}(G)$ and $F(C(\Gamma^+))$ which we denote by $\Psi(C_0(G), C(\Gamma^+))$ i.e.

$$\Psi(C_0(G), C(\Gamma^+)) = C^*(\mathcal{T}(G) \cup F(C(\Gamma^+)))$$

Using a Theorem of Power [9],[10] which characterizes the character space of the C^* -algebra generated by two C^* -algebras as a certain subset of the cartesian product of character spaces of these two C^* -algebras, we prove following theorem:

Main Theorem. *Let G be a non-compact, locally compact abelian Hausdorff topological group whose Pontryagin dual Γ is partially ordered and let Γ^+ be the semi-group of positive elements of Γ . Suppose that Γ^+ separates the points of G i.e. for any $t_1, t_2 \in G$ with $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$. Let*

$$\Psi(C_0(G), C(\Gamma^+)) = C^*(\mathcal{T}(G) \cup F(C(\Gamma^+)))$$

be the C^ -algebra generated by Toeplitz operators and Fourier multipliers on $H^2(G)$. Then for the character space $M(\Psi)$ of $\Psi(C_0(G), C(\Gamma^+))$ we have*

$$M(\Psi) \cong (\dot{G} \times \{\infty\}) \cup (\{\infty\} \times \dot{\Gamma}^+)$$

1. PRELIMINARIES

In this section we fix the notation that we will use throughout and recall some preliminary facts that will be used in the sequel.

Let S be a compact Hausdorff topological space. The space of all complex valued continuous functions on S will be denoted by $C(S)$. For any $f \in C(S)$, $\|f\|_\infty$ will denote the sup-norm of f , i.e.

$$\|f\|_\infty = \sup\{|f(s)| : s \in S\}.$$

If S is a locally compact Hausdorff topological space, $C_0(S)$ will denote the space of continuous functions f which vanish at infinity i.e. for any $\varepsilon > 0$ there is a compact subset $K \subset S$ such that $|f(x)| < \varepsilon$ for all $x \notin K$. For a Banach space X , $K(X)$ will denote the space of all compact operators on X and $\mathcal{B}(X)$ will denote the space of all bounded linear operators on X . The real line will be denoted by \mathbb{R} , the complex plane will be denoted by \mathbb{C} and the unit circle group will be denoted by \mathbb{T} . The one point compactification of a locally compact Hausdorff topological space S will be denoted by \dot{S} . For any subset $S \subset \mathcal{B}(H)$, where H is a Hilbert space, the C^* -algebra generated by S will be denoted by $C^*(S)$ and for any subset $S \subset A$ where A is a C^* -algebra, the closed two-sided ideal generated by S will be denoted by $I^*(S)$.

For any $\phi \in L^\infty(G)$ where G is a Borel space (a topological space with a regular measure on it), M_ϕ will be the multiplication operator on $L^2(G)$ defined as

$$M_\phi(f)(t) = \phi(t)f(t).$$

For convenience, we remind the reader of the rudiments of theory of Banach algebras, some basic abstract harmonic analysis and Toeplitz operators.

Let A be a Banach algebra. Then its character space $M(A)$ is defined as

$$M(A) = \{x \in A^* : x(ab) = x(a)x(b) \quad \forall a, b \in A\}$$

where A^* is the dual space of A . If A has identity then $M(A)$ is a compact Hausdorff topological space with the weak* topology. When A is commutative $M(A)$ is called the maximal ideal space of A . For a commutative Banach algebra A the Gelfand transform $\Gamma : A \rightarrow C(M(A))$ is defined as

$$\Gamma(a)(x) = x(a).$$

If A is a commutative C^* -algebra with identity, then Γ is an isometric *-isomorphism between A and $C(M(A))$. If A is a C^* -algebra and I is a two-sided closed ideal of A ,

then the quotient algebra A/I is also a C*-algebra (see [5]). For a Banach algebra A , we denote by $\text{com}(A)$ the closed ideal in A generated by the commutators $\{a_1a_2 - a_2a_1 : a_1, a_2 \in A\}$. It is an algebraic fact that the quotient algebra $A/\text{com}(A)$ is a commutative Banach algebra. The reader can find detailed information about Banach and C*-algebras in [11] and [5] related to what we have reviewed so far.

On a locally compact abelian Hausdorff topological group G there is a unique (up to multiplication by a constant) translation invariant measure λ on G i.e. for any Borel subset $E \subset G$ and for any $x \in G$,

$$\lambda(xE) = \lambda(E)$$

where $xE = \{xy : y \in E\}$ is the translate of E by x . This measure is called the Haar measure of G . Let $L^1(G)$ be the space of integrable functions with respect to this measure. Then $L^1(G)$ becomes a commutative Banach algebra with multiplication as the convolution defined as

$$(f * g)(t) = \int_G f(ts^{-1})g(s)d\lambda(s)$$

The Pontryagin dual Γ of G is defined to be the set of all continuous homomorphisms from G to the circle group \mathbb{T} :

$$\Gamma = \{\gamma : G \rightarrow \mathbb{T} : \gamma(st) = \gamma(s)\gamma(t) \text{ and } \gamma \text{ is continuous}\}$$

It is a well known fact that Γ is in one to one correspondence with the maximal ideal space $M(L^1(G))$ of $L^1(G)$ via the Fourier transform:

$$\langle \gamma, f \rangle = \hat{f}(\gamma) = \int_G \overline{\gamma(t)}f(t)d\lambda(t)$$

When Γ is topologized by the weak* topology coming from $M(L^1(G))$, Γ becomes a locally compact abelian Hausdorff topological group with point-wise multiplication as the group operation:

$$(\gamma_1\gamma_2)(t) = \gamma_1(t)\gamma_2(t)$$

Let $\tilde{\lambda}$ be a fixed Haar measure on Γ . Plancherel theorem asserts that the Fourier transform \mathcal{F} is an isometric isomorphism of $L^2(G)$ onto $L^2(\Gamma)$:

$$\mathcal{F}(f)(\gamma) = \hat{f}(\gamma) = \int_G \overline{\gamma(t)}f(t)d\lambda(t)$$

with inverse \mathcal{F}^{-1} defined as

$$\mathcal{F}^{-1}(f)(t) = \check{f}(t) = \int_\Gamma \gamma(t)f(\gamma)d\tilde{\lambda}(\gamma)$$

Here we note that $\tilde{\lambda}$ is normalized so that the above formula for the inverse Fourier transform holds. For detailed information on abstract harmonic analysis consult [12].

A partially ordered group Γ is a group with partial order \geq on it satisfying $\gamma_1 \geq \gamma_2$ implies $\gamma\gamma_1 \geq \gamma\gamma_2 \forall \gamma \in \Gamma$. This definition of the ordered group was given in [8]. Let $\Gamma^+ = \{\gamma \in \Gamma : \gamma \geq e\}$ be the semi-group of positive elements of Γ where e is the unit of the group Γ . Let G be a locally compact abelian Hausdorff topological group and let Γ be the Pontryagin dual of G . Then the Hardy space $H^2(G)$ is defined as

$$H^2(G) = \{f \in L^2(G) : \hat{f}(\gamma) = 0 \quad \forall \gamma \notin \Gamma^+\}$$

The Hardy space $H^2(G)$ is a closed subspace of $L^2(G)$ and since $L^2(G)$ is a Hilbert space, there is a unique orthogonal projection $P : L^2(G) \rightarrow H^2(G)$. For any $\phi \in L^\infty(G)$ the Toeplitz operator $T_\phi : H^2(G) \rightarrow H^2(G)$ is defined as

$$T_\phi = PM_\phi$$

Toeplitz operators satisfy the following algebraic properties:

- $T_{c\phi+\psi} = cT_\phi + T_\psi \quad \forall c \in \mathbb{C}, \quad \forall \phi, \psi \in C(\dot{G})$
- $T_\phi^* = T_{\bar{\phi}} \quad \forall \phi \in C(\dot{G})$

The proofs of these properties are the same as in the classical case where $G = \mathbb{T}$ (or $G = \mathbb{R}$) and can be found in [3].

The Toeplitz C^* -algebra $\mathcal{T}(G)$ is defined to be the C^* -algebra generated by continuous symbols on G :

$$\mathcal{T}(G) = C^*(\{T_\phi : \phi \in C_0(G)\} \cup \{I\})$$

where I is the identity operator and $C_0(G)$ is the space of continuous functions which vanish at infinity:

$$C_0(G) = \{f : G \rightarrow \mathbb{C} : f \text{ is continuous and } \forall \epsilon > 0 \quad \exists K \subset\subset G \mid |f(t)| < \epsilon \quad \forall t \notin K\}$$

where $K \subset\subset G$ denotes a compact subset of G . Actually one has

$$\mathcal{T}(G) = C^*(\{T_\phi : \phi \in C(\dot{G})\})$$

where \dot{G} is the one-point compactification of G . In the case where G is compact one has $G = \dot{G}$ and the most prototypical concrete example of this case is $G = \mathbb{T}$. This case was analyzed by Coburn in [1]. The famous result of Coburn asserts that for any $T \in \mathcal{T}(\mathbb{T})$ there are unique $K \in K(H^2(\mathbb{T}))$ and $\phi \in C(\mathbb{T})$ such that $T = T_\phi + K$. Hence the quotient algebra $\mathcal{T}(\mathbb{T})/K(H^2(\mathbb{T}))$ modulo the compact operators is isometrically isomorphic to $C(\mathbb{T})$. The two sided closed $*$ -ideal $com(G)$ generated by the commutators is called the commutator ideal of $\mathcal{T}(G)$:

$$com(G) = I^*(\{T_\phi T_\psi - T_\psi T_\phi : \phi, \psi \in C(\dot{G})\})$$

and the semi-commutator ideal $scom(G)$ is defined as

$$scom(G) = I^*(\{T_{\phi\psi} - T_\psi T_\phi : \phi, \psi \in C(\dot{G})\})$$

The symbol map $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/com(G)$ is defined as

$$\Sigma(\phi) = [T_\phi]$$

where $[\cdot]$ denotes the equivalence class modulo $com(G)$. In [2] and [8] it is shown that Σ is an isometry. The symbol map Σ also preserves the $*$ operation however is not a homomorphism i.e does not preserve multiplication. But if $com(G) = scom(G)$ then it is an isometric isomorphism. We will show under certain conditions that $com(G) = scom(G)$.

We introduce another class of operators which we call the ‘‘Fourier multipliers’’. This class of operators in the case $G = \mathbb{R}$ was introduced in [4] and proved to be useful in calculating the essential spectra of a class of composition operators. The Fourier multiplier $D_\theta : H^2(G) \rightarrow H^2(G)$ with symbol $\theta \in C(\Gamma^+)$ is defined as

$$D_\theta(f)(t) = (\mathcal{F}^{-1}M_\theta\mathcal{F}(f))(t)$$

The most prototypical example of a Fourier multiplier is a convolution operator with kernel $k \in L^1(G)$:

$$(T_k f)(t) = \int_G k(ts^{-1})f(s)d\lambda(s)$$

It is not difficult to see that actually $T_k = D_{\hat{k}}$ where \hat{k} denotes the Fourier transform of k . The set of all Fourier multipliers $F(C(\Gamma^+))$ defined as

$$F(C(\Gamma^+)) = \{D_\theta : \theta \in C(\Gamma^+)\}$$

is a commutative C*-algebra since the map $D : C(\Gamma^+) \rightarrow F(C(\Gamma^+))$ defined as $D(\theta) = D_\theta$ is an isometric *-isomorphism.

Lastly we consider the C*-algebra generated by Toeplitz operators and Fourier multipliers. Let $\Psi(C_0(G), C(\dot{\Gamma}))$ be the C*-algebra

$$\Psi(C_0(G), C(\dot{\Gamma})) = C^*(\mathcal{T}(G) \cup F(C(\Gamma^+)))$$

generated by Toeplitz operators with continuous symbols and continuous Fourier multipliers. The main result of this paper is a characterization of the character space $M(\Psi)$ of $\Psi(C_0(G), C(\dot{\Gamma}))$. We know that

$$M(F(C(\Gamma^+))) \cong \Gamma^+,$$

under certain conditions we have $scom(G) = com(G)$ and this implies that

$$M(\mathcal{T}(G)) \cong \dot{G}.$$

We will use the following theorem due to Power [9],[10] in identifying the character space of $\Psi(C_0(G), C(\Gamma^+))$:

Power's Theorem. *Let C_1, C_2 be C*-subalgebras of $B(H)$ with identity, where H is a separable Hilbert space, such that $M(C_i) \neq \emptyset$, where $M(C_i)$ is the space of multiplicative linear functionals of C_i , $i = 1, 2$ and let C be the C*-algebra that they generate. Then for the commutative C*-algebra $\tilde{C} = C/com(C)$ we have $M(\tilde{C}) = P(C_1, C_2) \subset M(C_1) \times M(C_2)$, where $P(C_1, C_2)$ is defined to be the set of points $(x_1, x_2) \in M(C_1) \times M(C_2)$ satisfying the condition:*

Given $0 \leq a_1 \leq 1, 0 \leq a_2 \leq 1, a_1 \in C_1, a_2 \in C_2$,

$$x_i(a_i) = 1 \quad \text{with} \quad i = 1, 2 \quad \Rightarrow \quad \|a_1 a_2\| = 1.$$

The proof of this theorem can be found in [9]. Power's theorem will give the character space $M(\Psi)$ of $\Psi(C_0(G), C(\dot{\Gamma}))$ as a certain subset of the cartesian product $\dot{G} \times \Gamma^+$.

2. THE CHARACTER SPACE OF $\Psi(C_0(G), C(\dot{\Gamma}))$

In this section we will concentrate on the C*-algebra $\Psi(C_0(G), C(\dot{\Gamma}))$. But before that we will identify the character space $M(\mathcal{T}(G))$ of $\mathcal{T}(G)$ under certain conditions. The condition that we will pose on G is that Γ^+ separate the points of G i.e. for any $t_1, t_2 \in G$ with $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$. Under this condition we show that $scom(G) = com(G)$ and this implies that $M(\mathcal{T}(G)) \cong \dot{G}$. Hence we begin by proving the following lemma whose proof is adapted from the proof of Theorem 2.2 of [6]:

Proposition 2. *Let G be a locally compact abelian Hausdorff topological group whose Pontryagin dual Γ is partially ordered and let Γ^+ be the semigroup of positive elements of Γ . Suppose that Γ^+ separates the points of G i.e. for any $t_1, t_2 \in G$ with $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$. Let $\text{com}(G)$ and $\text{scom}(G)$ be the commutator and the semi-commutator ideal of the Toeplitz C^* -algebra $\mathcal{T}(G)$ respectively. Then*

$$\text{com}(G) = \text{scom}(G)$$

Proof. It is trivial that $\text{com}(G) \subseteq \text{scom}(G)$ hence we need to show that $\text{scom}(G) \subseteq \text{com}(G)$:

Let $B = \{\phi \in C_0(G) : T_\phi T_\psi - T_{\phi\psi} \in \text{com}(G)\}$ then B is a self-adjoint subalgebra of $C_0(G)$: Let $\psi \in B$ then since

$$T_\phi T_{\bar{\psi}} - T_{\phi\bar{\psi}} = (T_\psi T_{\bar{\phi}} - T_{\bar{\phi}} T_\psi)^* + (T_{\bar{\phi}} T_\psi - T_{\bar{\phi}\psi})^*$$

we have $(T_\psi T_{\bar{\phi}} - T_{\bar{\phi}} T_\psi)^* \in \text{com}(G)$, $(T_{\bar{\phi}} T_\psi - T_{\bar{\phi}\psi})^* \in \text{com}(G)$ and hence $T_\phi T_{\bar{\psi}} - T_{\phi\bar{\psi}} \in \text{com}(G) \forall \phi \in C(\dot{G})$. This implies that $\bar{\psi} \in B$. It is clear that $\psi_1, \psi_2 \in B$ implies that $\psi_1 + \psi_2 \in B$. Let us check that $\psi_1 \psi_2 \in B$: we have

$$T_\phi T_{\psi_1 \psi_2} - T_{\phi \psi_1 \psi_2} = T_\phi (T_{\psi_1 \psi_2} - T_{\psi_1} T_{\psi_2}) + (T_\phi T_{\psi_1} - T_{\phi \psi_1}) T_{\psi_2} + (T_{\phi \psi_1} T_{\psi_2} - T_{\phi \psi_1 \psi_2}).$$

Since $\psi_1 \in B$ and $\text{com}(G)$ is an ideal we have $T_\phi (T_{\psi_1 \psi_2} - T_{\psi_1} T_{\psi_2}) \in \text{com}(G)$, $(T_\phi T_{\psi_1} - T_{\phi \psi_1}) T_{\psi_2} \in \text{com}(G)$ and $(T_{\phi \psi_1} T_{\psi_2} - T_{\phi \psi_1 \psi_2}) \in \text{com}(G)$ which implies that $T_\phi T_{\psi_1 \psi_2} - T_{\phi \psi_1 \psi_2} \in \text{com}(G) \forall \phi \in C_0(G)$. So we have $\psi_1 \psi_2 \in B$. Now we need to show that B separates the points of G to conclude the proof since in that case B is closed and by Stone-Weierstrass theorem we will have $B = C_0(G)$: Now let $A(G) = \{\psi \in C_0(G) : \psi f \in H^2(G) \forall f \in H^2(G)\}$. Clearly $A(G) \subseteq B$, hence if we show that $A(G)$ separates the points of G we are done. For any $k \in L^1(\Gamma^+)$ consider

$$\check{k}(t) = \int_{\Gamma^+} k(\gamma) \gamma(t) d\tilde{\lambda}(\gamma)$$

then since for any $f \in H^2(G)$ we have

$$\mathcal{F}(\check{k}f) = k * \hat{f}$$

the Fourier transform of $\check{k}f$ will be supported in Γ^+ . This implies that $\check{k} \in A(G)$. Since Γ^+ separates the points of G , $\{\check{k} : k \in L^1(\Gamma^+)\}$ also separates the points of G and hence $A(G)$ separates the points of G . This implies that B separates the points of G . This proves our lemma. \square

We have the following corollary of proposition 2:

Corollary 3. *Let G be a locally compact abelian Hausdorff topological group whose Pontryagin dual Γ is partially ordered and let Γ^+ be the semigroup of positive elements of Γ . Suppose that Γ^+ separates the points of G i.e. for any $t_1, t_2 \in G$ with $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$. Let $\mathcal{T}(G)$ be the Toeplitz C^* -algebra with symbols in $C(\dot{G})$ acting on $H^2(G)$. Then we have*

$$M(\mathcal{T}(G)) \cong \dot{G}$$

Proof. The symbol map $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/\text{com}(G)$, $\Sigma(\phi) = [T_\phi]$ is an isometry that preserves the $*$ -operation and $\Sigma : C(\dot{G}) \rightarrow \mathcal{T}(G)/\text{scom}(G)$ is multiplicative.

Since $\text{com}(G) = \text{scom}(G)$, Σ is an isometric isomorphism. Since characters kill the commutators we have

$$M(\mathcal{T}(G)) = M(\mathcal{T}(G)/\text{com}(G)) \cong M(C(\dot{G})) = \dot{G}$$

□

We will need the following small observation in proving our main theorem:

Lemma 4. *Let G be a locally compact, non-compact, abelian Hausdorff topological group and let $K_1, K_2 \subset G$ be two non-empty compact subsets of G . Then there is $t_0 \in G$ such that $K_1 \cap (t_0 K_2) = \emptyset$ where $t_0 K_2 = \{t_0 t : t \in K_2\}$.*

Proof. Since G is non-compact and locally compact there is a one-point compactification \dot{G} of G . Hence there is a point at infinity $\infty \in \dot{G}$ such that $\infty \notin G$. Assume that the lemma does not hold i.e. there are two non-empty compact subsets $K_1, K_2 \subset G$ such that $K_1 \cap (t K_2) \neq \emptyset$ for all $t \in G$. Now take a net $\{t_\alpha\}_{\alpha \in \mathcal{I}} \subset G$ such that $\lim_{\alpha \in \mathcal{I}} t_\alpha = \infty$. Since $\forall \alpha \in \mathcal{I}$ we have $K_1 \cap (t_\alpha K_2) \neq \emptyset$, there are $x_\alpha \in K_1$ and $y_\alpha \in K_2$ such that $x_\alpha = t_\alpha y_\alpha$. Since K_1 and K_2 are compact there are $x_0 \in K_1$, $y_0 \in K_2$ and sub-nets $x_{\alpha_1} \in K_1$, $y_{\alpha_2} \in K_2$ such that $\lim x_{\alpha_1} = x_0$ and $\lim y_{\alpha_2} = y_0$. One can further find a common sub-net index set $\mathcal{I}_0 \subset \mathcal{I}$ such that $\lim_{\beta \in \mathcal{I}_0} x_\beta = x_0$ and $\lim_{\beta \in \mathcal{I}_0} y_\beta = y_0$. Since $x_\beta = t_\beta y_\beta$, $\lim_{\beta \in \mathcal{I}_0} t_\beta = \infty$ and multiplication is continuous this implies that

$$x_0 = \lim_{\beta \in \mathcal{I}_0} x_\beta = \lim_{\beta \in \mathcal{I}_0} t_\beta y_\beta = \infty$$

but this contradicts to the fact that $x_0 \in K_1$. This contradiction proves the lemma. □

Now we will show the following lemma which will shorten the proof of our main theorem. The proof of the following lemma is adapted from [13]:

Lemma 5. *Let G be a locally compact abelian Hausdorff topological group with Pontryagin dual Γ . Let $\phi \in C_0(G)$ and $\theta \in C_0(\Gamma)$ each have compact supports. Then $D_\theta M_\phi$ is a compact operator on $L^2(G)$ where $D_\theta = \mathcal{F}^{-1} M_\theta \mathcal{F}$.*

Proof. Let $K_1 \subset G$ and $K_2 \subset \Gamma$ be compact supports of ϕ and θ respectively. Then for any $f \in L^2(G)$ we have

$$\begin{aligned} (D_\theta M_\phi f)(t) &= \int_{K_2} \gamma(t) \theta(\gamma) \left(\int_{K_1} \overline{\gamma(\tau)} \phi(\tau) f(\tau) d\lambda(\tau) \right) d\tilde{\lambda}(\gamma) \\ &= \int_{K_1} \left(\phi(\tau) \int_{K_2} \gamma(t\tau^{-1}) \theta(\gamma) d\tilde{\lambda}(\gamma) \right) f(\tau) d\lambda(\tau) = \int_{K_1} k(t, \tau) f(\tau) d\lambda(\tau) \end{aligned}$$

where

$$k(t, \tau) = \phi(\tau) \int_{K_2} \gamma(t\tau^{-1}) \theta(\gamma) d\tilde{\lambda}(\gamma)$$

Now consider

$$\begin{aligned} \int_G \int_G |k(t, \tau)|^2 d\lambda(t) d\lambda(\tau) &= \int_G \int_G \left| \phi(\tau) \int_{K_2} \gamma(t\tau^{-1}) \theta(\gamma) d\tilde{\lambda}(\gamma) \right|^2 d\lambda(t) d\lambda(\tau) \\ &\leq \|\phi\|_\infty^2 \int_{K_1} \int_G |\tilde{\theta}(t\tau^{-1})|^2 d\lambda(t) d\lambda(\tau) = \|\phi\|_\infty^2 \int_{K_1} \|\tilde{\theta}\|_2^2 d\lambda(\tau) \\ &= \|\phi\|_\infty^2 \int_{K_1} \|\theta\|_2^2 d\lambda(\tau) = \|\phi\|_\infty^2 \|\theta\|_2^2 \lambda(K_1) < \infty \end{aligned}$$

This implies that $D_\theta M_\phi$ is Hilbert-Schmidt and hence compact. \square

Now we are ready to prove our main theorem as follows:

Main Theorem. *Let G be a non-compact, locally compact abelian Hausdorff topological group whose Pontryagin dual Γ is partially ordered and let Γ^+ be the semi-group of positive elements of Γ . Suppose that Γ^+ separates the points of G i.e. for any $t_1, t_2 \in G$ with $t_1 \neq t_2$ there is $\gamma \in \Gamma^+$ such that $\gamma(t_1) \neq \gamma(t_2)$. Let*

$$\Psi(C_0(G), C(\dot{\Gamma}^+)) = C^*(\mathcal{T}(G) \cup F(C(\dot{\Gamma}^+)))$$

be the C^ -algebra generated by Toeplitz operators and Fourier multipliers on $H^2(G)$. Then for the character space $M(\Psi)$ of $\Psi(C_0(G), C(\dot{\Gamma}^+))$ we have*

$$M(\Psi) \cong (\dot{G} \times \{\infty\}) \cup (\{\infty\} \times \dot{\Gamma}^+)$$

Proof. We will use Power's Theorem. In the setup of Power's theorem $C_1 = \mathcal{T}(G)$ and $C_2 = F(C(\dot{\Gamma}^+))$. By corollary 3 we have $M(C_1) = \dot{G}$ and we have $M(C_2) = \dot{\Gamma}^+$. So we need to determine $(t, \gamma) \in \dot{G} \times \dot{\Gamma}^+$ satisfying for $0 \leq \phi, \theta \leq 1$, $\phi(t) = \theta(\gamma) = 1$ implies $\|T_\phi D_\theta\| = 1$.

Let $(t, \gamma) \in G \times \Gamma^+$. Let $\phi \in C(\dot{G})$, $\theta \in C(\dot{\Gamma}^+)$ such that $0 \leq \phi, \theta \leq 1$ and $\phi(t) = \theta(\gamma) = 1$. Let us also assume that θ and ϕ have compact supports. Let $\tilde{\theta} \in C(\dot{\Gamma})$ such that $0 \leq \tilde{\theta} \leq 1$, $\tilde{\theta}$ has compact support and $\tilde{\theta}|_{C(\dot{\Gamma}^+)} = \theta$. Since

$$\|T_\phi D_\theta\| \leq \|M_\phi D_{\tilde{\theta}}\|_{L^2(G)}$$

it suffices to show that $\|M_\phi D_{\tilde{\theta}}\|_{L^2(G)} < 1$. We will also assume that $\phi(s) < 1 \forall s \in G - \{t\}$. Since $(M_\phi D_{\tilde{\theta}})^* = D_{\tilde{\theta}} M_\phi$ and $D_{\tilde{\theta}} M_\phi$ is compact by Lemma 5, $M_\phi D_{\tilde{\theta}}$ is also compact. Hence $M_\phi D_{\tilde{\theta}} (M_\phi D_{\tilde{\theta}})^* = M_\phi D_{\tilde{\theta}}^2 M_\phi$ is a compact self-adjoint operator on $L^2(G)$ and this implies that $\|M_\phi D_{\tilde{\theta}}^2 M_\phi\| = \mu$ where μ is the largest eigenvalue of $M_\phi D_{\tilde{\theta}}^2 M_\phi$. Let $f \in L^2(G)$ be the corresponding eigenvector such that $\|f\|_2 = 1$, then we have

$$\mu = \|\mu f\|_2 = \|(M_\phi D_{\tilde{\theta}}^2 M_\phi f)\|_2 < \|D_{\tilde{\theta}}^2 M_\phi f\|_2 \leq 1$$

since $\phi(s) < 1 \forall s \in G - \{t\}$. This implies that $\|D_{\tilde{\theta}} M_\phi\|^2 = \|M_\phi D_{\tilde{\theta}}^2 M_\phi\| < 1$. This means that $(t, \gamma) \notin M(\Psi) \forall (t, \gamma) \in G \times \Gamma^+$. So if $(t, \gamma) \in M(\Psi)$ then either $t = \infty$ or $\gamma = \infty$.

Now let $t \in \dot{G}$ and $\gamma = \infty$. Let $\phi \in C(\dot{G})$ and $\theta \in C(\dot{\Gamma}^+)$ such that $0 \leq \phi, \theta \leq 1$ and $\phi(t) = \theta(\infty) = 1$. Observe that $P = D_{\chi_{\Gamma^+}}$ where χ_{Γ^+} is the characteristic function of Γ^+ . So we have $D_\theta T_\phi = D_\theta D_{\chi_{\Gamma^+}} M_\phi = D_{\chi_{\Gamma^+}} D_\theta M_\phi = D_\theta M_\phi$. Since \mathcal{F} is unitary we have

$$\|D_\theta M_\phi\|_{H^2(G)} = \|\mathcal{F} D_\theta M_\phi \mathcal{F}^{-1}\|_{L^2(\Gamma^+)} = \|M_\theta \mathcal{F} M_\phi \mathcal{F}^{-1}\|_{L^2(\Gamma^+)}$$

Since $\theta(\infty) = 1$ we have $\forall \epsilon > 0$, $\exists \gamma_0 \in \Gamma^+$ such that $1 - \epsilon \leq \theta(\gamma) \leq 1 \forall \gamma \geq \gamma_0$. Consider the operator $S_{\gamma_0} : L^2(\Gamma^+) \rightarrow L^2(\Gamma^+)$ defined as $(S_{\gamma_0} f)(\gamma) = f(\gamma_0^{-1} \gamma)$, then S_{γ_0} is an isometry. Observe that

$$\begin{aligned} (\mathcal{F}^{-1} S_{\gamma_0} f)(t) &= (S_{\gamma_0}^\sim f)(t) = \int_{\Gamma^+} \gamma(t) f(\gamma_0^{-1} \gamma) d\tilde{\lambda}(\gamma) \\ &= \int_{\Gamma^+} \gamma_0(t) u(t) f(u) d\tilde{\lambda}(u) = \gamma_0(t) \check{f}(t) = (M_{\gamma_0} \check{f})(t) \end{aligned}$$

Hence we have $S_{\gamma_0} = \mathcal{F}M_{\gamma_0}\mathcal{F}^{-1}$ which implies that

$$S_{\gamma_0}(\mathcal{F}M_{\phi}\mathcal{F}^{-1}) = (\mathcal{F}M_{\phi}\mathcal{F}^{-1})S_{\gamma_0}.$$

Now let $f \in L^2(\Gamma^+)$ such that $\|(\mathcal{F}M_{\phi}\mathcal{F}^{-1})f\|_2 > 1 - \epsilon$ and $\|f\|_2 = 1$ then for $g = \mathcal{F}M_{\phi}\mathcal{F}^{-1}f$ we have

$$\|M_{\theta}S_{\gamma_0}g\|_2 \geq (1 - \epsilon)^2$$

since $S_{\gamma_0}g$ is supported on $\{\gamma : \gamma \geq \gamma_0\}$, $\theta(\gamma) \geq 1 - \epsilon \forall \gamma \geq \gamma_0$ and $\|S_{\gamma_0}g\|_2 \geq 1 - \epsilon$. Since $S_{\gamma_0}g = (\mathcal{F}M_{\phi}\mathcal{F}^{-1})S_{\gamma_0}f$ we have

$$\|(M_{\theta}\mathcal{F}M_{\gamma_0}\mathcal{F}^{-1})(S_{\gamma_0}f)\|_2 \geq (1 - \epsilon)^2.$$

Since S_{γ_0} is an isometry we have $\|S_{\gamma_0}f\|_2 = 1$ and this implies that

$$\|M_{\theta}\mathcal{F}M_{\phi}\mathcal{F}^{-1}\| \geq (1 - \epsilon)^2$$

$\forall \epsilon > 0$. Therefore we have $\|M_{\theta}\mathcal{F}M_{\phi}\mathcal{F}^{-1}\| = \|D_{\theta}T_{\phi}\| = 1$. Hence $(t, \infty) \in M(\Psi)$ $\forall t \in \dot{G}$.

Now let $\gamma \in \Gamma^+$ and $t = \infty$. Let $\phi \in C(\dot{G})$ and $\theta \in C(\Gamma^+)$ such that $0 \leq \phi, \theta \leq 1$ and $\phi(\infty) = \theta(\gamma) = 1$. Since $\phi(\infty) = 1$, for any $\epsilon > 0$ there is a compact subset $K_1 \subset G$ such that $1 - \epsilon \leq \phi(t) \leq 1 \forall t \notin K_1$. Let $\tilde{\theta} = \chi_{\Gamma^+}\theta$. Then we have

$$D_{\theta}T_{\phi} = D_{\theta}D_{\chi_{\Gamma^+}}M_{\phi} = D_{\chi_{\Gamma^+}\theta}M_{\phi} = D_{\tilde{\theta}}M_{\phi}.$$

Let $\epsilon > 0$ be given. Let $g \in H^2(G)$ so that $\|g\|_2 = 1$ and $\|D_{\tilde{\theta}}g\|_2 \geq 1 - \epsilon$. Let $K_2 \subset G$ be a compact subset of G so that

$$\left(\int_{K_2} |g(t)|^2 d\lambda(t)\right)^{\frac{1}{2}} \geq 1 - \epsilon.$$

By Lemma 4 we have $t_0 \in G$ such that $K_1 \cap (t_0K_2) = \emptyset$. Let $(S_{t_0}g)(t) = g(tt_0^{-1})$ then $\left(\int_{t_0K_2} |S_{t_0}g(t)|^2 d\lambda(t)\right)^{\frac{1}{2}} = \left(\int_{K_2} |g(t)|^2 d\lambda(t)\right)^{\frac{1}{2}} \geq 1 - \epsilon$. and this implies that

$$\|S_{t_0}g - M_{\phi}S_{t_0}g\|_2 \leq 2\epsilon.$$

We observe that $S_{t_0} = \mathcal{F}^{-1}M_{\hat{t}_0}\mathcal{F}$ where $\hat{t}_0 : \Gamma \rightarrow \mathbb{C}$ defined as $\hat{t}_0(\gamma) = \gamma(t_0)$. This implies that S_{t_0} is unitary and we have $D_{\tilde{\theta}}S_{t_0} = S_{t_0}D_{\tilde{\theta}}$. Since $\|D_{\tilde{\theta}}\| = 1$ we have

$$\|D_{\tilde{\theta}}S_{t_0}g - D_{\tilde{\theta}}M_{\phi}S_{t_0}g\|_2 \leq 2\epsilon.$$

Since S_{t_0} is unitary for $f = S_{t_0}g$ we have $\|f\|_2 = 1$ and $D_{\tilde{\theta}}S_{t_0} = S_{t_0}D_{\tilde{\theta}}$ together with $\|D_{\tilde{\theta}}g\|_2 \geq 1 - \epsilon$ implies that

$$\|D_{\tilde{\theta}}M_{\phi}f\|_2 \geq 1 - 3\epsilon.$$

Since $\epsilon > 0$ is arbitrary we have $\|D_{\tilde{\theta}}M_{\phi}\| = \|D_{\theta}T_{\phi}\| = 1$. Therefore we have $(\infty, \gamma) \in M(\Psi)$, $\forall \gamma \in \Gamma^+$. Our theorem is thus proven. \square

3. ACKNOWLEDGEMENTS

The author wishes to express his sincere thanks to Prof. Rıza Ertürk of Hacettepe University for useful discussions on Lemma 4.
